

A Comparative Study on the Protective Role of Silymarin and Coenzyme-Q10 on the Cerebellar Cortex of Experimentally Induced Atherosclerosis in Adult Male Albino Rats: A Histological, Immunohistochemical and Biochemical Study

Nadia Said Badawy Khair and Seham Ahmed Mohammed Abdel Aziz

Department of Histology and Cell Biology, Faculty of Medicine, Menoufia University, Menoufia, Egypt

ABSTRACT

Background: Atherosclerosis is known as a serious cardiovascular condition that causes human mortality worldwide. Atherosclerosis is a significant progressive condition of inflammation. Atherosclerosis of the cerebellar arteries affects voice, balance and fine motor control. Coenzyme-Q10 vitamin soluble in fat that used for heart failure and angina treatment protocol. It has the potential to influence cellular bioenergetics, and counteract free radical damage. This has proven success in treating many neurodegenerative diseases. Silymarin is a flavonoid extract of the herb *Silybum marianum*. It has been reported as the gold medicine in liver disorders and evaluated recently as a neuroprotective.

Objective: Comparison of potential neuroprotective effects of Co Q10 and Silymarin on adult male albino rats cerebellar cortex suffering from atherosclerosis.

Materials and Methods: Sixty adult male albino rats were divided randomly into equal four classes: Group I (control group) subdivided into three subgroups: Subgroup IA: provided ordinary diet. Subgroup IB (Co enzyme Q10 treated): obtained ordinary diet and co-enzyme Q10 Subgroup IC (Silymarin treated): obtained ordinary diet and Silymarin. Group II (atherosclerotic group), Group III (atherosclerotic Co Q10 treated group) and Group IV (atherosclerotic Silymarin treated group). After three months, lipid profile was assessed in blood samples taken from all classes. Cerebellar cortices were processed for histological, biochemical, immunohistochemical and electron microscopic studies.

Results: Atherosclerotic rats showed loss and disruption of Purkinje cell layer with pyknotic nuclei, dilated cisternae of rough endoplasmic reticulum, prominent perineural spaces and spongiosis of granular and molecular layers. Significant increase in GFAP, Cox-2 immunoreactivity was also found. However, concomitant administration of Co Q10 or Silymarin had ameliorating effect on these changes.

Conclusion: Co Q10 or Silymarin supplementation had a neurological protective role in atherosclerosis. Silymarin may be the ideal neuroprotective agent and new approach for reduction of many neurological diseases in high risk population.

INTRODUCTION

Atherosclerosis (AS) is one of the cardiovascular conditions, causing mortality worldwide^[1]. This is a progressive inflammatory disease that causes vessel wall plaques to form; hinders the resulting supply of blood to the tissues^[2]. These plaques can remain silent for many decades, but may cause stenosis or rupture over time, leading to heart failure, myocardial infarction and stroke^[3]. Although, AS is a multi-factorial disorder, elevated cholesterol concentrations, transmitted primarily by LDL-C particles, facilitate atherosclerotic lesions^[4].

Ischemic cerebrovascular diseases (CVDs) and its complications are one of world's most incipient reasons of morbidity and mortality. It leads to cognitive decline and vascular dementia. Studies have shown that atherosclerotic disease is the cause of the ischemic CVDs^[5].

In the presence of elevated plasma low-density lipoprotein (LDL), plaques within the cranial arteries will build up. As a consequence, luminal stenosis can reduce or even block the blood supply to the brain, causing deficiencies of oxygen and energy substrates in the cerebral and cerebellar tissues^[6]. Control voice, fine motor coordination, and memory are impaired by cerebellar atherosclerotic arteries^[7].

Coenzyme-Q10 (CoQ10), (2,3-dimethoxy-5-methyl-6-decarpenyl benzoquinone) is a vitamin-like fat soluble quinone generally referred to ubiquinone. It is found throughout the body in various tissues, particularly in the skin, liver, kidney and pancreas^[8]. This is consumed in meats and fish, in limited quantities. It is widely used in treatment of angina and heart failure. CoQ10 has also been used to alleviate headache with migraine, Parkinson's disease and other disorders^[9]. It has an antioxidant function, which plays

a significant role in the metabolism and can affect cellular bioenergetics and mitigate the free radical damage^[10].

Silymarin (SM) is a flavonoid extract of a plant called *Silybum Marianum*. This is a lipophilic fruit extract and milk thistle's active complex^[11]. SM is formulated as a mixture of flavanolignan antioxidants. It is composed of four isomers of flavanolignan; silybin, silybinin, silydianin and silychristin. Silybin is amongst them the most active and the most widely used^[12]. Silymarin is consumed orally and is excreted as sulphates and conjugates primarily by bile. It has been identified as the gold drug for treatment of alcoholic hepatitis-related liver disorders and viral hepatitis^[13].

In addition to hepato-protection, many neurodegenerative lesions, as cerebral ischemia^[14], Parkinson's disease^[11] and Alzheimer's disease^[15] have recently been confirmed that SM a neuroprotective medication for treatment. This also exhibits additional benefits by affecting processes such as amyloid accumulation and apoptotic cellular machinery^[16].

It is well-known that the cerebellum control both posture and motion. Disorders of the cerebellum have an effect on muscle function and hinder body coordination. Also, it is found in other non-motor cognitive functions, as learning, sensory perception, memory and attention^[17]. Only a few studies have identified the effect of atherosclerosis (AS) on the cerebellum and on the clinical level. So, the present work aimed to study the structural changes which might result from induced atherosclerosis on the cerebellar cortex of adult male albino rats. Also to compare the possible neuroprotective effects of Co Q10 versus Silymarin in adult male albino rats, suffering from atherosclerosis, using histological, biochemical and immunohistochemical studies.

MATERIALS AND METHODS

The present study was carried out on sixty adult male albino rats, average age of 2-3 months and weighing 180-200 gms each. They had been installed in stainless steel in a room at standard temperature. They were allowed free access to ad-libitum water and rat chow throughout the experiment. Strict sanitation and precautions have been taken to keep them in a safe, natural climate. The animals were observed daily for general condition and behavior. Animal care was based on ethical guidelines accepted by the Menoufia Faculty of Medicine Ethical Committee.

Experimental procedure

The animals were divided into four groups, 15 animals each: Group I (control group): it was consisted of 15 adult rats that was subdivided equally into three subgroups:

Subgroup IA: animals were left untreated and provided an ordinary diet.

Subgroup IB (Co enzyme Q10 treated): each rat obtained an ordinary diet and co-enzyme Q10 at a dose of 1mg by oral gavage^[10]. Co enzyme Q10 (Ubiquinone): 200 mg bottle in liquid form was obtained from Pharco Pharmaceutical Company (Cairo, Egypt).

Subgroup IC (Silymarin treated): each rat obtained an ordinary diet and Silymarin powder dissolved in sterile water and taken orally with a dosage of 100 mg / kg body weight through the gastric tube^[11]. Silymarin powder obtained from sigma-Aldrich, USA

Group II (atherosclerotic induced group): received an ordinary diet with 1% cholesterol powder for three months to induce^[18]. Cholesterol powder (3 β -Hydroxy-5-cholestene) from Sigma Aldrich Co., Germany, developed cholesterol powder (approximately 99%) and catalog number (57-88-5): 100g in a polycontainer.

Group III (atherosclerotic Co Q10 treated group): Received an ordinary diet with 1% cholesterol powder in the same dose and route of administration of group II, concomitant with Co-enzyme-Q 10 in the same dose and route of administration of subgroup IB.

Group IV (atherosclerotic Silymarin treated group): each rat provided an ordinary diet with 1% cholesterol powder in the same dose and route of administration of group II, simultaneously with Silymarin in the same dose and route of administration of subgroup IC.

The rats were fed their respective diets for three months and had water ad libitum. Experimental animals' body weights were assessed at the beginning of the experiment, and after 3 months. They were fasted for 10h at end of experiment but water was not limited.

At the appropriate time, all rats were anaesthetized and perfused transcardiac with 4% paraformaldehyde in 0.1 M PBS (phosphate buffered saline) followed by 4 % cold paraformaldehyde in 0.1 M PBS for 10 min^[19]. Blood samples obtained from orbital venous plexus, centrifuged for 20 min. Carefully opened the skulls and separated cerebelli, then dissected cerebellar cortices. Specimens of cerebellar cortices postfixed in 10 per cent of formalin buffered for light microscopic analysis. Other specimens, postfixed for ultrastructural examination in 2.5 per cent phosphate-buffered glutar-aldehyde. For biochemical analysis of tissue, sections of cerebellar cortices are stored in liquid nitrogen for the assessment of endogenous antioxidant and oxidative markers.

Histological study

Tissue samples for light microscopic analysis were then washed and processed for preparation of paraffin section. Sections were cut and stained with hematoxylin and eosin (H&E) for histological examination^[20].

Immunohistochemical study

Glial fibrillary acidic protein immunostaining (GFAP) for detection of astrocytes Sections of paraffin were deparaffinised, rehydrated and endogenous peroxidase activity blocked in absolute alcohol for 45 min with 0.05 per cent hydrogen peroxide. In order to reveal the antigen sites, the slides were placed in (PBS) for 7 min, and were put in a microwave with citrate buffer for 10 min. In bovine serum albumin, the slides were incubated in PBS dissolved for 30

min to avoid unspecific staining of the history. Then, the parts were incubated for 90 min with the primary antibodies. Antibody GFAP has been put to the pieces. Slides were rinsed in PBS, incubated with anti-mouse immunoglobulins for 60 min, combined with a peroxidase-labeled dextran polymer^[21]. Control negative parts treated by with PBS, with all other steps being carried out in the same way. Normal brain was used to regulate the GFAP positively^[21].

PCNA immunohistochemical staining

Nuclear proliferating cell antigen (PCNA) ,an intranuclear polypeptide included in replication, repair and excision of DNA. Cell proliferation is related to its synthesis and expression^[22]. In PCNA (Clone PC 10, DAKO A / S Denmark), immunohistochemical staining was performed using primary antiserum. In Trisbuffered saline the primary antibody was diluted with a dilution of 1:50, as defined by the data sheet. The parts incubated in + 4 ° C overnight with the primary antibody. Its binding was observed using a generic, manufacturer-recommended avidin biotin-peroxidase detection method (DAKO, Carpinteria, USA). Instead of the primary antibody a mouse monoclonal antibody was added to serve as a negative buffer. Small intestines have been used for effective regulation. Then the slides were stained with diaminobenzene (DAB) as the chromogenic, counterstained with hematoxylin^[22].

Cyclooxygenase-2 (Cox-2) immunohistochemical staining

COX-2 expression was observed by using the main anti-rabbit antibody, COX2-specific anti-mouse polyclonal IgG (SAB4200576; Sigma). Parts of the cerebellar cortices were dewaxed, hydrated and endogenous peroxidase activity was blocked in methanol with 0.3 per cent hydrogen peroxide. In antibody diluent (Cat. # IW-1000 or # IW-1001),the primary antibody parts incubated for 1 h at room temperature. Parts have been rinsed with PBS 3 times. Applied hydrogen peroxide covers the section for 5 min, and slides were gently put in PBS. Adequate volume of primary antibody (dilution 1: 200) was added to the specimens, which were incubated afterwards. The slides were then rinsed into PBS. Biotinylated connection has been placed and parts have been rinsed with PBS. Streptavidin horseradish peroxidase reagent, sprayed for 10 min, then rinsed in PBS. Freshly prepared 3, 3'- diaminobenzidine chromogenic substrate solution was placed on the specimens for 10 min. Sections then sprayed with distilled water and counterstained with Mayer's hematoxyline after being dried, dehydrated, cleaned and placed by DPX in tap water. Save for the use of the primary antibody^[23], negative tests were treated as the same procedure. Parts prepared from control animal kidney tissue were used as positive COX-2 test slides^[23].

Electron microscopic study

Cerebellar parts (1mm³) were cut ,fixed in 3 per cent glutaraldehyde with 0.1 mol / l PBS at 4 ° C for transmission electron microscope (TEM) analysis. Parts were dehydrated

in ethanol, purified in propylene oxide, coated with epon. Semi-thin parts of toluidine blue were cut and dyed in. Parts of ultrathin had been cut and treated with uranyl acetate and lead citrate^[24]. A Jeol- JEM- 100 CXII; Joel, Tokyo, Japan, studied the ultra-structure of the tissues. TEM processing and analysis were performed at the Unit of Electron Microscopy, Faculty of Medicine, Tanta University.

Biochemical study

Blood samples obtained from orbital venous plexus, centrifuged for 20 min then blood sera used to triglyceride, total cholesterol, LDL-cholesterol and HDL cholesterol, determinations. The spectrophotometer was used to calculate both of these parameters. Cortices of cerebellum were excised, immersed in liquid nitrogen to freeze for 1 h at -70 °C. In ice cold phosphate buffer, frozen tissue was homogenized and centrifuged. The supernatant was used as the antioxidant markers to test tissue superoxide dismutase (SOD)^[25] and catalase (CAT)^[26]. They were determined using commercial kits (Bio Diagnostic Company, Dokki, and Giza, Egypt, respectively) ,catalog no. 2520, 2516. Malodialdehyde concentration (MDA) has been calculated as an indicator of lipid peroxidation and oxidant stress^[27].

Morphometric study and Statistical analysis

The interactive image analyzer measurement menu (LeciaQwin 500 image analyser computer program, England) in the Department of Anatomy, Faculty of Medicine, University of Menoufia, used to test these parameters in all studied classes.

1. Counting the nuclei of Purkinje cells by millimeter length in the segment^[28].
2. Immunostaining strength of GFAP and Cox-2 was assessed in immunostained areas. All of the above parameters were calculated by total magnification of ×400 using 10 readings from 5 non-overlapped sections from each rat of 5 rats randomly selected. The biochemical and morphometric results were analyzed and compared by student's t-test. *P-value* for the significant change in each parameter in the experimental animals to check according to control group. Data were tabulated as mean ± SD, analyzed using statistical (SPSS) software (version 17.0 on an IBM compatible computer; SPSS Inc., Chicago, Illinois, USA). *P value* was calculated at 0.05, *P>0.05* was non-significant, while *P value<0.05* significant and *P value <0.001* was highly significant^[29].

RESULTS

General appearance and survival

Observation of rats during the experimental period revealed that high cholesterol diet was well tolerated by the rats and no mortality was detected. Rats of all groups exhibited normal activities. They had smooth and glossy fur and did not have any neurological signs.

Mean weight in grams in different groups

At the end of the experiment, there was a highly significant increase ($p < 0.001$) in the mean weight of atherosclerotic rats (group II) comparing with the control groups. There was a significant decrease ($P < 0.05$) in the mean weight in atherosclerotic Co Q10 treated group (group III) as compared with atherosclerotic group. In addition, atherosclerotic Silymarin treated rats (group IV) showed a highly significant decrease ($p < 0.001$) in the mean weight when compared to atherosclerotic rats (group II) (Table 1).

Histological results

H&E sections of the cerebellum of group (I) showed the well-known normal structure. Each cerebellar folium consisted of outer gray matter (cerebellar cortex) and inner white matter. The cerebellar cortices of animals of subgroups IA, IB and IC showed the normal histological architecture of the rat cerebellar cortex with no difference between them. Each cortex is formed of outer molecular, middle Purkinje cell layer, inner granular layer (Figure 1). The Molecular layer formed mainly of fibers, stellate and basket cells. The Purkinje cells were arranged in a single row between the molecular and granular layers. The inner granular layer showed aggregation of small tightly packed cells with dark spherical nuclei among pale areas, called cerebellar islands. Small blood capillaries were also seen in this layer (Figure 2). Purkinje cells showed large pyriform cell bodies containing large rounded vesicular nuclei with prominent nucleoli and pale acidophilic cytoplasm with scattered basophilic Nissl granules. The granular layer formed of numerous crowded small granular cells with darkly stained nuclei and scanty cytoplasm (Figure 3). H&E stained cerebellar sections of atherosclerotic group (group II) revealed disruption of the Purkinje cell layer. Most of Purkinje cells were shrunken having irregular outlines with deep homogenous cytoplasm with absence of Nissl granules and having darkly stained pyknotic nuclei. Other Purkinje cells were lost, leaving empty spaces, surrounded by neuroglia cells. Regular stellate and basket cells and congested dilated blood vessels were also noticed in the molecular layer (Figures 4,5). There were prominent perineural spaces around Purkinje, basket and stellate cells. Numerous vacuolations in the granular and molecular layers (Spongiosis) were also noticed (Figure 5).

On the other hand, group III analysis (atherosclerotic coenzyme Q10 treated) showed that most Purkinje cells had a similar appearance to control group appearance. However, some Purkinje cells still affected. The granular layer was apparently normal. However, slight vacuolations in the molecular layer were still present (Figure 6).

H&E stained cerebellar portions of atherosclerotic Silymarin treated rats (group IV) showed the cortical layers looking more or less as in control group. Purkinje cells retained their normal linear organization. They contained pale vesicular nuclei and prominent nucleoli. The granule cells appear nearly similar to the control. No observable differences from control group were noticed in the granular

and molecular layers (Figure 7). In addition, Purkinje cells retained its normal shape and size (Figure 8).

Electron microscopic examination of the cerebellar cortices of control rats revealed normal Purkinje cells with its characteristic large size. They had euchromatic nuclei with prominent nucleoli. Their cytoplasm had mitochondria, lysosomes, free ribosomes and strands of rough endoplasmic reticulum (Figure 9). Electron microscopic examination of granular layer of control group, revealed that granule cells had rounded nuclei having peripheral clumps of heterochromatin, free ribosomes and mitochondria (Figure 10).

Ultrathin sections of the molecular layer of cerebellar cortex of control rats showed that, almost all nerve fibers are surrounded by normal myelin sheath and having mitochondria (Figure 11). Cerebellar cortices of both Co Q10 and Silymarin-treated rats demonstrated no ultrastructural difference from control group.

Cerebellar sections of atherosclerotic rats showed a shrunken Purkinje cell having flat indented nucleus, dilated cisternae of rough endoplasmic reticulum, cytoplasmic vacuoles and many electron dense vesicles (Figure 12). Granule cells contained increased nuclear chromatin condensation, free ribosomes destructed mitochondria with disruption of myelinated nerve fibers (Figure 13). In addition, some granule cells had small pyknotic nuclei with areas of vacuolated cytoplasm (Figures 13,14), while other cells were apoptotic with presence of vascular congestion (Figure 14). The molecular layer showed disruption and dissociation of the myelinated nerve fibers with degenerated mitochondria in some fibers (Figure 15). Electron microscopic examination of the cerebellar cortex of atherosclerotic rats treated with co Q10 revealed Purkinje cell having euchromatic nucleus with apparent nucleolus, cisternae of rough endoplasmic reticulum, numerous small ribosomes.

However, degenerated mitochondria and some cytoplasmic vacuoles are still present (Figure 16). Nearly normal granule cells, having rounded nuclei and surrounded by a shell of cytoplasm were seen. Other cells with increased nuclear chromatin condensation and dilated cisternae of rough endoplasmic reticulum. The myelinated nerve fibers surrounded the cells, were more or less normal (Figure 17). The molecular layer contained nearly intact normal myelinated nerve fibers. While, few myelinated nerve fibers with slight distortion of its myelin sheath were still present (Figure 18).

In atherosclerotic Silymarin-treated group (group IV), Purkinje cells exhibited similar ultrastructural appearance of the control; euchromatic nuclei, prominent nucleoli and well-defined nuclear envelope. Cytoplasm containing free ribosomes, mitochondria and rough endoplasmic reticulum (Figure 19). The granular cells appeared more or less normal and showed round or oval nuclei and peripheral masses of heterochromatin, mitochondria and free ribosomes (Figure 20). Myelinated nerve fibers were nearly like of control group (Figures 20,21).

Immunohistochemical results

GFAP immunohistochemical staining (astrocyte detection) of cerebellar cortices of control rats, Co Q10 and Silymarin -treated rats showed scattered GFAP positive cells in the molecular and granular layers with mild positive immune reaction (Figure 22a). However, group II (atherosclerotic) showed abundant large GFAP positive cells with strong positive immune reaction, mainly in the molecular layer and granular layer compared to the control (Figure 22b). GFAP immunostaining of astrocytes in group III(atherosclerotic co Q10) showed decreased positive staining, giving moderate positive immune reaction (Figure 22c) while GFAP immunostaining of astrocytes of group IV(atherosclerotic Silymarin) showed decreased positive staining , giving mild positive immune reaction (Figure 22d).

PCNA immunohistochemical staining of cerebellar cortices of control rats (group I) showed strong nuclear intensity of Purkinje cells and granule cells for PCNA immunostaining (Figure 23a). In addition, cerebellar cortices of Co Q10 and of Silymarin-treated rats showed the same appearance as control group. However, rats of atherosclerotic group (group II) showed negative nuclear reaction of Purkinje cells and mild positive nuclear immune reaction for PCNA immunostaining in granule cells compared with control group (group I) (Figure 23b). While, strong positive nuclear immune reaction of PCNA in Purkinje cells and granule cells was observed in the cerebellar cortices of both group III(atherosclerotic Co Q10 –treated group) and group IV (atherosclerotic Silymarin-treated group) (Figures 23c,d).

Immunohistochemically stained sections for Cox-2 of cerebellar cortices of rats of control group (group I) showed low cytoplasmic intensity of immune reaction for COX-2 of the molecular layer, Purkinje cells and the granule cells (Figure 24a).In atherosclerotic (group II), strong +ve high-intensity COX-2 immune reaction was seen in granular layer, Purkinje cells and molecular layer (Figure 24b). Moderate intensity immune reaction of COX-2 in group III (atherosclerotic Co Q10 –treated group) was seen in all layers (Figure 24c). While, group IV (atherosclerotic Silymarin- treated group) showed mild –intensity immune reaction of Cox-2 in all layers (Figure 24d).

Biochemical results

There was a non-significance difference between subgroups of control animals. While the atherosclerotic induced group (group II) recorded a highly significant increase($p<0.001$) in serum level of both triglycerides, LDL-C and total cholesterol in comparison to control groups, while, level of HDL-C significantly decreased ($P<0.05$) when compared with control groups,. However, in atherosclerotic

Co Q10 (group III) and atherosclerotic Silymarin treated rats (group IV), the serum level of triglycerides, LDL-C and total cholesterol showed a highly significant decrease ($p<0.001$), while HDL-C level was increased significantly ($P<0.05$) when compared with atherosclerotic animals (Table 2).

Atherosclerotic rats (group II) showed a highly significant reduction ($p<0.001$)of all antioxidant markers; SOD, CAT and a highly significant increase in oxidative marker MDA when compared to control. However, atherosclerotic Co Q10 group (group III) and atherosclerotic Silymarin group (group VI),demonstrated a highly significant increase in CAT and SOD while, level of MDA showed a highly significant decrease compared to atherosclerotic (group II) (Table 3, Histogram 1).

Morphometric results

Data in (Table 4) showed that there was no significance difference between the control subgroups. The atherosclerotic rats (group II) exhibited a highly significant ($P<0.001$) decrease of mean total number of Purkinje cells compared to control group. Rats of atherosclerotic Co Q10 (group III) showed significant increase ($P<0.05$) of number of Purkinje cells with comparison with atherosclerotic (group IV). While rats of atherosclerotic Silymarin (group IV) exhibited a highly significant ($P<0.001$) increase in Purkinje cells in comparison to atherosclerotic (group II) (Table 4, Histogram 2).

Data in (Table 5, Histogram 3) demonstrated that there was no significance difference between the control subgroups. The atherosclerotic rats (group II) exhibited a highly significant ($P<0.001$) increase of intensity of GFAP immunereaction of cerebellar cortex, compared to control. While, on administration of coQ10 to atherosclerotic rats (group III), they exhibited a highly significant decrease of intensity of GFAP immunereaction in comparison with atherosclerotic group (group II). However, cerebellar cortex of rats of group IV(Atherosclerotic Silymarin treated) revealed highly significant decrease ($P<0.001$) in intensity of GFAP immunereaction with comparison with the atherosclerotic group (group II).

In addition, (Table 5, Histogram 3) also showed that there was no significance difference between the control subgroups. The atherosclerotic rats (group II) exhibited highly significant increase ($P<0.001$) of intensity of Cox-2 immunereaction in cerebellar cortex, when compared with the control group. However, rats of the atherosclerotic Co Q10 treated (group III) and atherosclerotic Silymarin treated (group IV) showed significant decrease ($P<0.05$) of intensity of Cox-2 immunereaction in comparison with the atherosclerotic rats (group II).

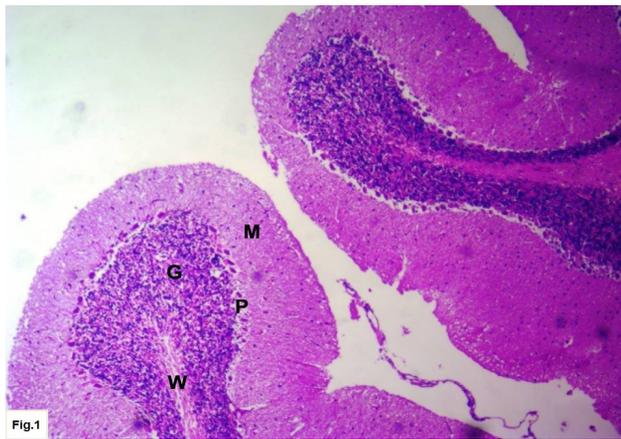

Fig. 1: A photomicrograph of cerebellar section of control rat (group I) showing cerebellum folium formed of outer gray matter, consists of molecular (M), Purkinje cell layer (P), and granular layer (G) and the inner white matter (W). (H&E X100)

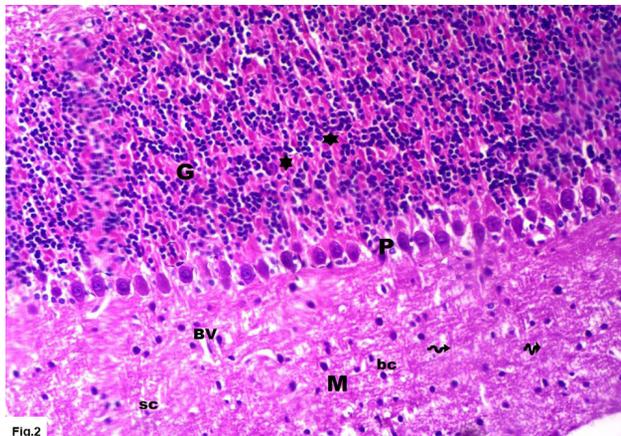

Fig. 2: A photomicrograph of section of cerebellar cortex of control rat (group I) showing outer molecular layer (M), containing fibers (zigzag arrow), basket cells (bc) and stellate cells (sc). The middle Purkinje cell layer (P), arranged in single row. granular layer (G) formed of aggregation of tightly packed small cells with dark spherical nuclei among pale areas, called cerebellar islands (stars). Note presence of small blood capillary (BV) in the molecular layer. (H&E X200)

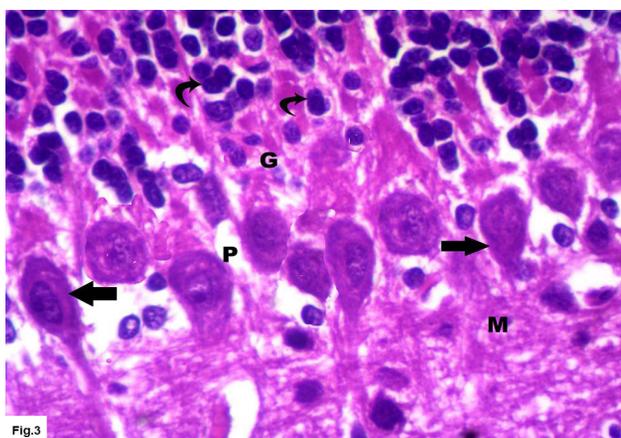

Fig. 3: A photomicrograph of section of cerebellar cortex of control rat showing part of molecular layer (M), Purkinje (P) cell layer consists of large pyriform cells, containing large rounded vesicular nuclei with prominent nucleoli and pale acidophilic cytoplasm with scattered basophilic Nissl granules (arrows). The granular layer (G), composed of well-defined clumps of small rounded cells with deeply stained nuclei and scanty cytoplasm (curved arrows). (H&E X400)

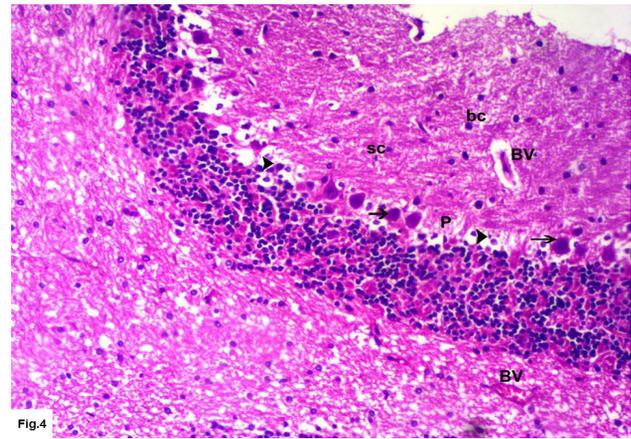

Fig. 4: A photomicrograph of section of cerebellar cortex from atherosclerotic rat (group II) showing disruption of Purkinje cell layer (P). Irregular -shaped Purkinje cells with deep homogenous cytoplasm and absence of Nissl granules with darkly stained pyknotic nuclei (arrows) are seen. Other Purkinje cells are lost, leaving empty spaces, surrounded by neuroglia cells (arrowheads). Frequent stellate cells (sc) and basket cells (bc) also observed. Notice congested blood vessel (BV). (H&E X200)

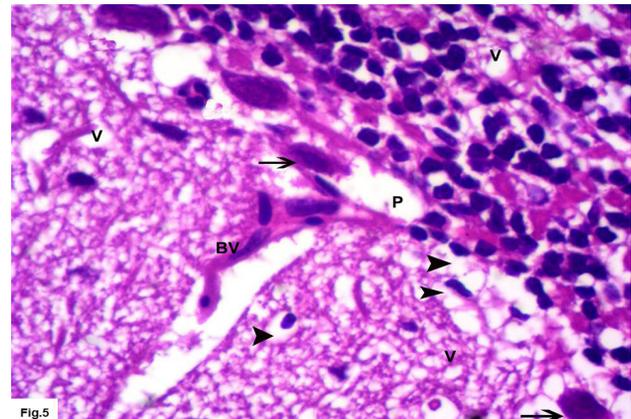

Fig. 5: A photomicrograph of section of cerebellar cortex from atherosclerotic rat showing Purkinje cells having darkly stained nuclei and cytoplasm (arrows) in Purkinje cell layer (P). Perineural spaces (arrowheads) are present around Purkinje, stellate cells and basket cells. Vacuolations (V) of molecular and granular layers are also present. Notice congested dilated blood vessel (BV). (H&E X400)

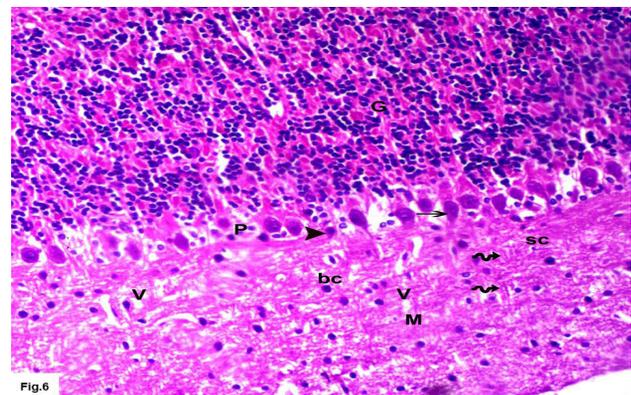

Fig. 6: A photomicrograph of section of cerebellar cortex of atherosclerotic rat treated with Coenzyme Q10 (group III) showing most of Purkinje cells (arrows) in the Purkinje cell layer (P), having appearance similar to control group. However, some Purkinje cells are irregular and darkly stained (arrowheads). Molecular layer (M) consists of fibers (zigzag arrows), small basket (bc) and stellate (sc) cells. Granular layer (G) is apparently normal. Note slight vacuolations (V) of the molecular layer. (H&E X200)

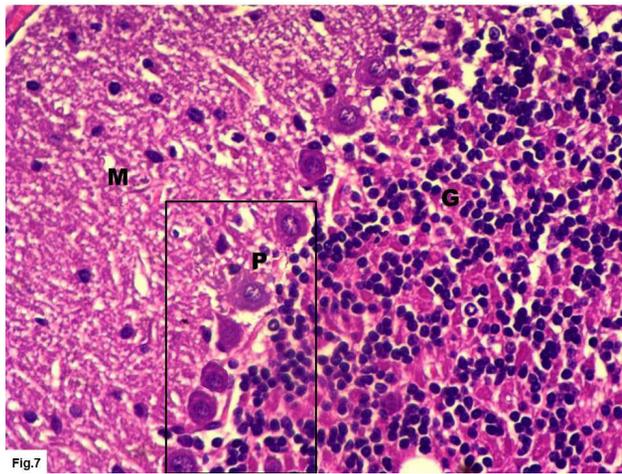

Fig. 7: A photomicrograph of section of cerebellar cortex of atherosclerotic Silymarin treated rat (group IV) showing Purkinje cell layer (P), granular layer (G) and molecular layer (M) having an appearance similar to control group. (H&E X200)

DISCUSSION

Atherosclerosis (AS) is a complex arterial wall disease induced by development of plaques that contribute to progressive arterial occlusion and ischemia. In this study, three months of cerebellar atherosclerosis and ischemia were effectively caused by daily intake of hypercholesterolemic diet, proven by measured elevated levels of triglycerides and total plasma cholesterol in rats. Dietary cholesterol induces elevated levels of cholesterol in the blood, leading to lesions in the arterial wall^[30]. The International Society for Atherosclerosis recommends decreasing

dietary cholesterol as a strategy for lowering low-density lipoprotein cholesterol (LDL-C). It was reported that dietary cholesterol increases cardiovascular diseases (CVDs) risk^[31]. A variety of experiments in rats fed with high cholesterol diet have observed a rise in plasma atherogenic lipids as plasma triglycerides and total cholesterol levels^[32]. The current results showed that body weight increased significantly in the atherosclerotic group compared with the normal group. Previous researches have shown that dietary factors, particularly the consumption of a high fat diet (HFD) is considered a risk factor for development of obesity^[33]. In addition^[34], explained that consumption of hypercholesterolemic diet facilitates the development of a positive energy balance leading to an increase in visceral fat deposition, abdominal obesity and body weight gain. Moreover,^[32] found that high cholesterol feeding is accompanied by molecular adaptations that favor fat storage in muscle rather than oxidation that in turn cause obesity.

The cerebellar cortex of atherosclerotic animals displayed robust structural lesions in the cell layer of Purkinje, which are consistent with Abd El-Samad's findings^[35]. Such changes in Purkinje cells revealed pathological loss of the cerebellar cortex's chief cells, which are the only cells in the cerebellum that supply information to other parts of the brain^[36]. Atherosclerotic rats showed Purkinje cell layer disruption with shrinking and loss of some of Purkinje cells leaving empty spaces around them. It had a smooth indented nucleus, and its cytoplasm comprises dilated cisterns of rough endoplasmic reticulum, vacuoles and several thick vesicles with electrons. This was consistent with^[37] which stated that cerebellar cells grown with cholesterol in cell culture induced neurodegeneration as indicated by altered morphology, reduced synaptic connections, and cell shrinkage compared with normal cells. Throughout this research, perineuronal spaces are found around Purkinje cells, basket and stellate cells. A previous work^[38] reported presence of such spaces.

The multiple electron dense bodies may be degenerated mitochondria, the product of auto-phagocytosis accompanied by lysosomal processing. This is considered a major degrading Mitochondria pathway^[39]. In several neurodegenerative diseases mostly associated with oxidative damage^[40], mitochondrial alterations and dysfunctions were identified. There was also a significant decrease in Purkinje cells number which is coincided with other studies who found that the Purkinje cell number and density is decreased in neurodegenerative diseases as AD^[28].

Some granule cells having pyknotic nuclei, damaged mitochondria and vacuolated cytoplasm appeared in this sample, as well as other apoptotic granular cells. Excessive cholesterol results in apoptosis, and death of cells^[37]. Moreover^[41] demonstrated that apoptosis was observed in multiple neurodegenerative diseases. These changes may be due to ischemia and cerebellar artery atherosclerosis as a result of a high intake of cholesterol. The degenerative changes of granule cells may be secondary to those of Purkinje cells^[42] stated that affected Purkinje cells had no normal contact with granular cells, resulting in loss of

normal synchronism between the two types of cells, thus minimizing their regulatory function. In the present findings, the observed condensation of nuclear chromatin agrees with reports from other investigators who reported that dying neurons may undergo chromatin condensation and dissolution^[17].

Some researchers have described vacuolation observed in Purkinje and granular cells as a result of significant disruptions in lipid inclusions^[43]. Other researchers indicated that vacuolation may be caused by cell injury, resulting in increased development of reactive oxygen species (ROS) that likely invaded the membranes and altered their permeability^[44]. Other studies have shown that lipid peroxidation considered autocatalytic process contributes to cellular membranes oxidative destruction which in turn contributes to development of toxic free radicals and cell death. Malondialdehyde (MDA) was the most important of those free radicals^[45].

Myelin defects considered a cause for reduced nerve impulse transmission and brain disorders found in cerebellar atherosclerosis. Obstruction of the nerve feeding vessels by atherosclerosis causes death of nerve bundles and loss of myelin^[46].

Immunohistochemical staining has confirmed the observed histological and ultrastructural results. Due to neuronal damage caused by atherosclerosis, activation of Bergmann astrocytes were seen as increased GFAP expression. Astrocytes were found to respond rapidly to any threat to the nervous system by developing various neurotoxic substances and further GFAP production. Such results have been used as a protein marker for astrocytosis^[47]. The observed features of reactive astrocytes in the present research could be due to compensatory mechanism following neurodegeneration. Related neurotoxicity processes were recorded^[48]. Astrocytosis was the key immunohistochemical characteristic observed in the rabbit brain fed with a high diet of cholesterol^[47]. Excessive cholesterol may explain astrocytosis by causing rigidity and loss of membrane fluidity in neurons, and cell debris formation. The developed debris function as antigen and activate the gliosis and inflammatory response^[49]. Astrocytes had been involved in the neuronal homeostasis cycle, and activation of glial cells may result as a secondary mechanism of cell death or neuroprotective response^[47]. Similar findings have been reported previously by^[50] who observed GFAP up-regulation in brain ischemia and necrosis after injection of cholesterol into internal carotid artery of rats.

The atherosclerotic community result of immunohistochemical staining has shown strong positive reaction for COX-2 in the current analysis. This pathogenic COX-2 effect is caused by inflammation-mediated injury^[51]. Similarly^[52] observed that COX-2 is markedly up-regulated in many brain pathological conditions, consistent with both in *vitro* and in *vivo* inflammation and cytotoxicity. Multiple neuropathologies as chronic neurodegenerative diseases associated with high positive COX-2 expression.

High expression of COX-2 is adaptive response in several conditions as inflammatory diseases and oxidative stress^[53].

PCNA is a nuclear protein, composed of 40% cyclin-D and cyclin-dependent kinase, It is strongly associated in the nuclear region where DNA synthesis and repair occurs. It is important in DNA replication and damage repair and it is not only is a cell cycle regulator but it also plays a part in cellular repair processes^[54]. In comparison with control animals, PCNA immunostained parts of group II (atherosclerotic) revealed negative immune reaction of Purkinje cells and mild positive immune reaction in granule cells. Similarly,^[55] found poor expression of PCNA in surviving cells affected by transient cerebral ischemia in brain regions.^[56] further claimed that PCNA is important in repair of DNA damage during cell cycle. In addition,^[54] demonstrated that altered functional state of PCNA protein in the ischemia-sensitive neurons suggesting that DNA repair processes are affected in these post-mitotic cells following ischemia. He also suggested that impaired DNA repair may play a role in the development of post-ischemic neuronal damage. Also, consistent with our result^[57] found that oxidative stress induces DNA damage in both the mitochondrial and nuclear genomes with subsequent week expression of PCNA protein.

The antioxidant enzymes are necessary in preventing and neutralizing oxidative damage caused by radicals. SOD and CAT are major protection factors against free radicals^[58]. The present biochemical study showed that feeding high cholesterol diet induced reduction of CAT and SOD and significant increase of MDA when compared to control group. In accordance with our findings^[45] stated that hypercholesterolemia enhances oxidative stress development and increases LPO through marked elevation in plasma MDA levels. These findings were consistent with earlier work that showed that cholesterol metabolites are cytotoxic and produce reactive oxygen species (ROS)^[59].

In the current research, microscopic light and electron analysis of parts of the atherosclerotic co Q 10 treated group showed that they restored almost their usual general architecture except for a few changes that are still present. Co Q 10 is involved in the elimination and prevention of oxidative stress-induced apoptosis by the reactive oxygen species. It also decreases inflammation and improves neuro-protection. Co Q10 significantly reduces the death of apoptotic cells^[60].

The present biochemical analysis of blood showed that high cholesterol diet in rats induced a significant increase in the serum level of both triglycerides and LDL-C while total cholesterol showed a highly significant increase, However, HDL-C significantly reduced.

Serum triglyceride level, LDL-C and total cholesterol showed a substantial decrease in the atherosclerotic Co Q10 rat, but HDL-C increased when compared with atherosclerotic community. Singh *et al.*^[61] reported that due to inhibition of LDL-C oxidation, Co Q10 decreases lipid levels and increases in HDL-C levels and decreases

oxidative stress^[62]. The present decrease in lipid profile values due to prevention hepatic synthesis of cholesterol, transfer of plasma cholesterol to liver, or regulation of lipid utilization^[61]. Coenzyme-Q 10 supplementation resulted in a significant increase in antioxidant markers while the level of oxidative marker MDA showed a significant decline relative to the atherosclerotic community. Such findings were consistent with preceding work^[63].

Co-administering Silymarin in this study soothed the neurotoxic effects of atherosclerosis on the cerebellum. In the group treated with atherosclerotic Silymarin (Group IV), the histological pattern almost identical to the control group was found. Microscopic light and electron analysis of this group's cerebellar cortex of rats revealed a more or less normal picture of Purkinje cells, molecular and granule cell layers. Purkinje cells were arranged in a single row and maintained their distinctive pyriform shape. Silymarin was found, in another study, to inhibit oxidative stress in brains of aged and young rats^[64]. It greatly inhibit degradation of proteins in animals' cerebral cortex and hippocampus. It was also considered a potent anti-inflammatory agent which modulates the various cells involved in this process^[65]. Additionally, Silymarin had documented being able to protect microglia and astroglia against oxidative insults^[66]. Compared to control rats, the morphometric results of atherosclerotic- Silymarin treated group showed no significant changes.^[67] Claimed that Silymarin had various mechanisms as an antioxidant; by direct free radical scavenging, through prevention development of free radicals, inhibition of particular enzymes and maintaining mitochondrial integrity of electron transport mechanism. Others however indicated that Silymarin's ability to decrease oxidative stress due to its protective effect on function and structure of the mitochondrial system^[68].

From all the evidences and findings, we can conclude that atherosclerosis caused by a high cholesterol diet has a deleterious impact and has adversely affected the cerebellar cortex of rats proved by histological, immunohistochemical, biochemical and histomorphometric changes. Cholesterol ratio nutritional knowledge in diet and concomitant administration of Co Q10 or Silymarin will protect against these dangerous effects of atherosclerosis.

On comparison between these two neuroprotectives, it was proposed that Silymarin could be an ideal neuroprotective agent against several conditions where neuronal damage was the product of oxidative stress by inhibiting neurological deficits and apoptosis responses. The treatment may be also a new method for reducing neurological manifestations in high-risk populations.

الملخص العربي

دراسة مقارنة للتأثير الوقائي المحتمل لعقار السيليمارين وأنزيم Q10 على تصلب الشرايين المستحث في قشرة مخيخ ذكور الفئران البيضاء البالغة: دراسة هستولوجية ، وهستوكيميائية مناعية وبيوكيميائية

قسم الهستولوجي وبيولوجيا الخلية – كلية الطب البشرى – جامعة المنوفية

تصلب الشرايين هو أحد أمراض القلب والأوعية الدموية الرئيسية. فهو أحد أكثر أسباب الوفيات في العالم. ويعتبر تصلب الشرايين مرض التهابي تدريجي، فتصلب شرايين المخيخ يؤثر على الكلام والتوازن والتحكم الحركي الدقيق. ان انزيم Q10 هو انزيم قابل للذوبان في الدهون. ويتم استخدامه في قصور القلب والذبحة الصدرية. كما أن له القدرة علي التأثير في الطاقة الحيوية الخلوية ومواجهة بعض الأضرار التي تسببها الشوارد الحرة. كما أظهر فعالية في علاج بعض الأمراض العصبية.

أما عقار السيليمارين فهو فلافونويد مشتق من نبات سيليبوم ماريانوم. وقد سجل كدواء ذهبي في اضطرابات الكبد وقيم مؤخرًا كعامل حماية عصبية.

الهدف من البحث: الهدف من هذا العمل هو مقارنة التأثيرات الوقائية المحتملة لأنزيم Q10 وعقار السيليمارين علي قشرة المخيخ للجرذان الذكور البيضاء البالغين، الذين يعانون من تصلب الشرايين.

المواد والطرق: تم استخدام ستون من ذكور الجرذان البيضاء البالغة، وقد قسمت عشوائيا الي أربع مجموعات متساوية، المجموعة الأولى (مجموعة ضابطة) حيث قسمت الي ثلاث مجموعات فرعية، (أ) أعطيت الغذاء المعتاد، و(ب) أعطيت أنزيم Q10 بجانب الغذاء المعتاد، و(ج) تناولت عقار السيليمارين مع الغذاء المعتاد. المجموعة الثانية (مجموعة تصلب الشرايين)، المجموعة الثالثة (مجموعة تصلب الشرايين وأنزيم Q10)، والمجموعة الرابعة (مجموعة تصلب الشرايين والسيليمارين). بعد ثلاثة أشهر، تم أخذ عينات دم من جميع المجموعات لتقييم مستوي الدهون، كما تم معالجة قشرة المخيخ لدراستها هستولوجيا وبيوكيميائيا وهستوكيميائية مناعية وبالمجهر الالكتروني.

النتائج: أظهرت الفئران التي تعاني من تصلب الشرايين فقدان وتعطيل خلايا بركينجي، مع احتوائها علي أنوية داكنة، واتسعت الشبكة الاندوبلازمية المحببة، توسع وبروز الفراغات المحيطة بالخلايا، ووجود فجوات اسفنجية في الطبقة الحبيبية والجزئية. كما وجد زيادة واضحة في صبغة GFAP وصبغة كوكس-2 الهستوكيميائية المناعية، ومع ذلك فان العلاج المتزامن بأنزيم Q10 أو عقار السيليمارين، كان له تأثير محسن علي هذه التغيرات.

الاستنتاج: اعطاء أنزيم Q10 أو عقار السيليمارين كان لهما دور وقائي عصبي في حالة تصلب الشرايين. وقد لوحظ أن عقار السيليمارين قد يكون عامل الحماية العصبية المثالي ونهج جديد للحد من التغيرات العصبية في الأشخاص المعرضين لخطر الاصابة بتصلب الشرايين.
