### **Abstract**

As part of an on-going study of the helminth parasites collected from the Red Sea fishes, *Apharyngogyliachaen callyodontis* Yamaguti, 1942 is reported for the first time parasitizing the middle and lower parts of the intestinal tract of *Scarus psittacus* (Common parrotfish) (Forsskål), collected from the northern Red Sea of Egypt. The encountered helminth was re-described morphologically and morphometrically based on the light microscope study. The current study demonstrated that some taxonomically important, previously unreported morphological and morphometric features, including the variation in; intestinal ceca length, and their posterior extension, testes position relative to ventral sucker, cirrus-sac shape, pars prostatica shape and its extension inside cirrus, genital pore positions from median to nearly submedian, vitelline follicles distribution and its posterior extension, seminal receptacle shape, ovary shape and posterior extension of the uterus. The diagnostic morphological features were elucidated and discussed to provide correct identification of *Apharyngogyliachaen* species with very careful consideration to avoid overlapping with the closely related species.

**Keywords:** *Apharyngogyliachaen callyodontis*; Common parrotfish; Egypt; Red Sea; *Scarus psittacu*.

## Introduction

*Apharyngogylianchen* Yamaguti, 1942 was erected for *Apharyngogylianchen callyodontis* Yamaguti, 1942 from the intestine of an unidentified parrotfish (“*Callyodon* sp.”) from off Naha, Okinawa, Japan, characterizing by absence of the oesophageal bulb (= “pharynx” of Yamaguti [1942]) and the intermediate position of its reproductive organs between closely related genera *Gylianchen* Nicoll, 1915 and *Paragylianchen* Yamaguti, 1934. (Yamaguti, 1942). Later, on the basis of those two distinctive features, Yamaguti (1958) proposed a new subfamily Apharyngogyliancheninae Yamaguti, 1958. In 1962, Manter and Pritchard erected another gylianchenine, the *Leptobulbus* Manter & Pritchard, 1962, differentiating from *Apharyngogylianchen* only by the presence of a uniquely, weakly developed oesophageal bulb (= “pharynx” of Manter and Pritchard [1962]) which represented an intermediate state between *Apharyngogylianchen* and other gylianchenide genera that have well-developed oesophageal bulbs. Therefore, Manter and Pritchard (1962) felt unsatisfactory to recognize Apharyngogyliancheninae as a distinct subfamily and reassigned again *Apharyngogylianchen* into Gyliancheninae. Hall & Cribb (2005) investigations followed Manter and Pritchard (1962) reassignment and clarified that *Apharyngogylianchen* has the same diagnostic features of the Gyliancheninae Fukui, 1929 and indicated no value in the recognition of a monotypic subfamily for *Apharyngogylianchen*. Cu & Shen (1983) added another two species from the Xisha islands in the South China Sea; *Apharyngogylianchen opisthovarius* Gu & Shen, 1983 from the intestine of an unidentified Wrasses fish (“*Cirrhilabrus*

sp.”) and *Apharyngogylianchen scarustis* Gu & Shen, 1983 from the intestine of Daisy parrotfish, *Scarus sordidus*. Wang (1977) recognized *Gylianchen thalassamae* from the Sixbar wrasse, *Thalassoma Hardwicke*], off China Sea and characterized it from the other *Gylianchen* spp. by its long ceca and absence of the oesophageal bulb (= “pharynx” of Wang [1977]) and on the basis of the later feature, Hall & Cribb (2005) investigations reassigned *G. thalassamae* Wang, 1977 inside *Apharyngogylianchen* as *Apharyngogylianchen thalassamae* (Wang, 1977) Hall & Cribb, 2005.

As part of an on-going study of the Digenea parasitizing the Red Sea fishes (see Khalifa et al., 2015; Dronen et al. 2016; Blend et al. 2017; Khalifa et al., 2018), *A. callyodontis* Yamaguti, 1942 was redescribed and its comparative metric account by several authors is also given and discussed.

## Materials and Methods

### Sampling

A total of 8 alive Common parrotfish, *Scarus psittacus* caught by small trawl at Sharm El-Naga, Makadi Bay, Southern Hurghada, Egypt (27°15'26.57"N, 33°48'46.48"E), during a period from 17 May 2012 to 2 September 2012 were screened for the presence of trematodes immediately after capture at the zoology laboratory, Faculty of Science, South Valley University.

### Parasitological investigation

The captured fish were dissected, and the intestines were removed and examined under American Optical Forty Model 41–48 stereomicroscope for the presence of endohelminths. Some specimens were observed alive. Adult worms were flattened

under very slight coverslip pressure in hot 5% buffered formal saline solution (Garcia and Ash, 1979), and preserved in 70% alcohol. Whole-mounts were stained with acetocarmine, cleared in Xylene, mounted in DPX and studied under a light microscope. Additionally, drawings were made with the aid of a Zeiss Universal compound microscope using micro-projector or camera Lucida (PZO 01852 10x). All measurements are given in micrometers ( $\mu\text{m}$ ). The recovered parasites were morphologically identified according to available literature; Hall and Cribb (2005). Furthermore, the prevalence was calculated according to Bush et al. (1997) and abundance and mean intensity according to Margolis et al. (1982). Additionally, the host fish was identified according to criteria established by Randall (1982), Lieske and Myers (1994, 1996) and Lieske et al. (2004). Fish identification authorities through the FishBase (Froese and Pauly 2019).

## Results

### Family Gyliachenidae Fukui, 1929

Syns. Dissotrematidae Goto & Matsudaira, 1918; Robphildollfusiidae Paggi & Orecchia, 1963

### Subfamily Gyliacheninae Fukui, 1929

Syns. Apharyngogyliacheninae Yamaguti, 1942; Ichthyotreminae Caballero & Bravo-Hollis, 1953

### Genus *Apharyngogyliachen* Yamaguti, 1942

*Apharyngogyliachen callyodontis* Yamaguti, 1942.

Host: Common parrotfish, *Scarus psittacus* (Forsskål) (Perciformes: Scaridae).

Locality: Northern Red Sea, off Sharm El-Naga, Makadi Bay, Southern Hurghada, Egypt (26°55'N, 33°56'E–26°54'N, 33°59'E; depth = 0.5–2.5 m; 17/May/2012 to 02/September/2012).

Site of infection: Middle and lower section of the intestinal tract.

Deposited material: Zoology Department, Faculty of Science, South Valley University (SVU), Qena, Egypt.

Prevalence: 6 of 8 (75% infected).

Intensity: 1–27, 103 worms.

Mean intensity: 59.67 (358/6).

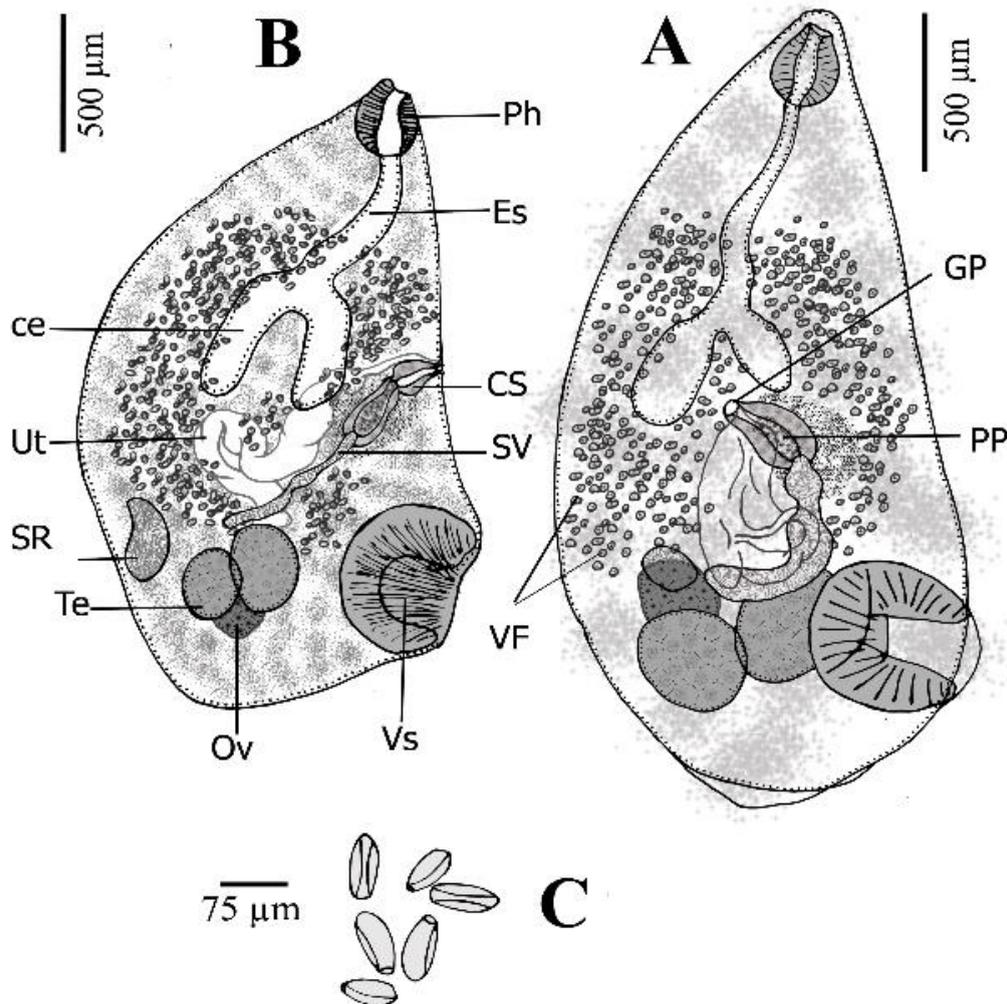

Relative density/abundance: 44.75 (258/8).

### Re-Description (Fig. 1, a-c)

[Based on 12 mature specimens.]  
Body fleshy, robust, yellowish orange in life, Horn-like in lateral view to pyriform in ventral view, dorsoventrally curved, with almost smooth and straight margins, maximum width at the level of mid-ventral sucker or slightly anterior to it. The anterior end was tapering; the posterior end was less truncated to almost round. Tegument was smooth. The most morphological feature is the absence of Oral sucker and it was replaced by the well-developed pharynx. The pharynx is elliptical to oval, subterminal or slightly terminal with conspicuous, oval aperture directed anteroventrally. Ventral sucker sessile, unspecialized, spherical to subspherical, subterminal, at ovary level or slightly anterior, distinctly larger than pharynx and situated at the anterior half of the last body third. The hind body is very short. Oesophagus fairly long, wide, less than 1/4 of body length straight, extends from the base of the pharynx to end of the anterior third level of the body and surrounded by numerous glandular esophageal cells along its length. The oesophageal bulb was absent. The intestinal bifurcation was found

at the anterior third level of the body, distinctly very distant from the ventral sucker. Ceca 2, simple, equal in length with the same width along its length and terminating blindly; bifurcates nearly at the end of the first third of the body.

Testes two rounded to elliptical, entire, smooth, subequal, side-by-side or slightly oblique, at the level of the ventral sucker to slightly posterior, situated at the anterior half of the last body third, well-separated from the posterior end. Seminal

**Fig. 1.** *Apharyngogyliachaen callyodontis* Yamaguti, 1942. **A**, voucher from *Scarus psittacus*, northern Red Sea off Egypt, ventro-lateral view; **B**, voucher from *Scarus psittacus*, northern Red Sea off Egypt, lateral view. **C**, elongate-oval operculated eggs. *Abbreviations.* Ph, pharynx; Es, esophagus; Ce, cecum; VS, ventral sucker; Te, testis; SV, seminal vesicle; CS, cirrus sac; GP, genital pore; PP, pars prostatica; Ov, ovary; SR, seminal receptacle; Ut, uterus.

vesicle tubular, often concealed by the uterus, bipartite, dumb-bell-shaped. Both two parts separated by a narrow constriction; distal portion occasionally perpendicular to the proximal portion. Most of the seminal vesicle external to the cirrus-sac and the distal extremity of the second part of the seminal vesicle is partly internal to cirrus-sac and enters it posteriorly. Cirrus-sac moderate in size, well-developed, claviform, extends in an obliquely vertical direction, extends from the beginning of the last third of intestinal caeca and terminates at the posterior level of caecal ends by a short distance. Pars prostatica dark-stained, well-developed, oval, occupy about posterior half of the cirrus-sac. Dense numbers of prostate cells surround almost of the cirrus-sac and anterior third of the distal portion of the seminal vesicle. Ejaculatory duct relatively short, tubular and straight. Genital atrium present. Genital pore equatorial, submedian (sinistral), anterior to mid-ceca level directly, (at the midpoint of body length).

Ovary entire, rounded, smooth, sinistro-submedian, immediately at the testicular level or slightly separated by a short distance. Seminal receptacle conspicuous, claviform, overlaps sinistral testis, immediately posterodorsal and sinistral to the ovary, larger than the ovary. Uterus extends anteriorly from mid-testicular and mid-ventral sucker level to mid-body, primarily intercecal, winding but not expansive, slightly coiled, restricted to the area among ovary, seminal receptacle, seminal vesicle, anterior margins of testes and genital pore. Uterus extends anteriorly as short, narrow metraterm parallel to the sinistral side of cirrus-sac and opens dorsolateral to it in the genital atrium. Vitellarium were follicular; field extends along lateral margins of body, a short distance post-pharynx to the level of the ovary or slightly posterior to anterior

margins of testes. confluent in the anterior portion of vitellaria especially anterior region of caeca and, overlaps intestinal caeca, the outer lateral margins of uterus and cirrus-sac and anterior margins of the ovary and seminal receptacle. Follicles were numerous, moderately dense, relatively small, spherical to subspherical in shape. Eggs were relatively few, moderately dense, oval in shape, moderate in size, operculated, thin-shelled, without filaments.

The excretory vesicle was saccular, claviform, extends anteriorly to reach the posterior margin of testes. The excretory pore was terminal. No excretory papilla was present.

#### Remarks

The present material is placed within *Apharyngogyliauchen* on the basis of presences of amphistomatous body-plan, a pre-testicular ovary, pyriform body, and absence of both oesophageal bulb and excretory papilla (Hall and Cribb, 2005). Comparison among newly collected specimens and the previously mentioned species indicated that present specimens matched *A. callyodontis* in overall appearance, egg size range, possessing submedian and post-bifurcate genital pore, alike in vitellarium distribution and parasitizing in the same host group. In addition, a large number of allometric measurements very similar and clearly with converge ranges included body width, pharynx length, ovary length, and pre-testicular distance as a percentage of body length as well as mean testes width/Ovary width ratios very identical.

*A. callyodontis* specimens in the current study are characterized from all previously described forms by having a smaller body size of both body and the internal organs; a ventral sucker is further

anterior relative to the testes, a dumb-bell-shaped seminal vesicle, and a dark-stained Pars prostatica. Furthermore, few allometric variations included slightly higher values in oesophagus length, post-testicular distance and pre-vitelline distance as a percentage of body length, and mean testes length/Ovary length ratio. In addition, slightly lower values observed in testes length as a percentage of body length.

## Discussion

Several morphological variations have been observed among all described sets of *A.s callyodontis* which in need to be considered carefully to avoid miss identifications when an *Apharyngogyliauchen* material recognized due to the overlap of some these features with the corresponding features in other *Apharyngogyliauchen* spp. Those variations included: [i] The difference in intestinal ceca length changed from longer, about 2/3 length of the body (Yamaguti, 1942) to shorter, did not exceed 50% of body length (Nagaty, 1956; Ramadan, 1986; Rabie and Ahmed, 2000; present study). [ii] The extension of cecal ends varied from just reaching or slightly overlapping the anterior border of testes (Yamaguti, 1942; Nagaty, 1956; Ramadan, 1986), to extend to the mid-ovarian level (Rabie and Ahmed, 2000) or being distant from the anterior border of testes as in present specimens. [iii] Testes position relative to ventral sucker differentiated into three positions, side-by-side and anterolateral to ventral sucker (Yamaguti, 1942; Ramadan, 1986), opposite or slightly diagonal and dorsal to ventral sucker (Nagaty,1956) and testes side-by-side at level of ventral sucker or slightly posterior (Rabie and Ahmed,2000; present study). [iv] Cirrus-sac shape distinguished among truncated elliptical (Yamaguti, 1942), a pyriform

(Nagaty,1956; Ramadan, 1986; Rabie and Ahmed,2000) and a claviform in the present study.[v] In addition, Pars prostatica exhibited several variations in both shape and its extension range inside cirrus-sac from being ovoid to elliptical and partly to entirely outside cirrus-sac (Yamaguti, 1942; Ramadan, 1986; Rabie and Ahmed,2000 ), to be fan-shaped and inside cirrus-sac (Nagaty,1956), or a dark-stained ovoid or elliptical and completely inside cirrus-sac as in the present study. [vi] Genital pore positioned into two very close positions, a sinistro-submedian position (Yamaguti, 1942; Rabie and Ahmed,2000; present study) and median position (Nagaty,1956; Ramadan, 1986). [vii] Seminal receptacle shape showed up a wide range of variability included a retort-shaped (Yamaguti, 1942), an oval shape (Nagaty,1956), equally bipartite (Ramadan, 1986) and a claviform as in the present study. [viii] The posterior extension of the vitelline field exhibited slight variations included extending of vitellaria to the ends of the ceca/ovary level (Yamaguti, 1942, Fig. 25; Rabie and Ahmed,2000, Fig. 4a; Present study) or vitellaria reaching further posterior to the level of the testes (Nagaty,1956, Fig. 4; Ramadan, 1986, Fig. 2). [ix] Ovary in all described forms of *A. callyodontis* was an oval to rounded except in Rabie and Ahmed (2000), it was irregular, maybe subtriangular anteriorly. [x] Uterus extension revealed either a pre-acetabular position (Yamaguti, 1942; Nagaty, 1956; Rabie and Ahmed, 2000) or the uterine loops extend to the mid-ventral sucker level (Ramadan, 1986; present study).

As known that differences in morphometric features (e.g. body length and width, ventral sucker width, etc.) can be symptomatic of host-induced variability. Measurements, morphometric percentages and morphometric ratios of *A. callyodontis*

All dimensions, measurements, and percentages are calculated to [0] decimal places; all ratios are calculated to 2 decimal places.

Range values are given first followed by the mean value. %\* percentage of body length.

--- = Neither given in the original description nor available from published illustrations.

<sup>a</sup> Calculated from measurements given in the original description.

<sup>b</sup> Calculated from illustration in the original description (see Yamaguti, 1942, Fig. 25; Nagaty, 1956, Fig. 4; Ramadan, 1986, Fig. 2; Rabie and Ahmed, 2000, Fig. 4a).

in Table 1 were listed from six different hosts, 4 scarids (*Callyodon* sp., *H. harid*, *S. ghobban*, *S. psittacus*) and two labrids (*A. caeruleopunctatus*, *C. abudjubbe*) so the slight variability among these measurements across these host species is due to host-induced variability. Furthermore, the data included in Table 1 reported from considerably two distant localities; one record from Japanese water (Yamaguti, 1942) and four records from the Red Sea off Egypt (Nagaty, 1956; Ramadan, 1986; Rabie and Ahmed, 2000; present study) which may have a contributed role in the intraspecific variability.

Hall and Cribb (2008) investigations on Gyliachenidae specimen preparation referred that the flattening process of

specimens often causes a distortion of the internal morphology, particularly of the reproductive system and can obscure gross morphological features. Furthermore, “the preparation of dorsoventral wholemounts is often impossible to achieve without fracture of the posterior half of the body”. Therefore, with the presence different procedures used during *A. callyodontis* specimens preparation in some publications and absence detailed information on how *A. callyodontis* specimens killed or on the methods used for *A. callyodontis* specimen preparation in other publications, we may consider that the observed differences in the intestinal ceca length, posterior extension ceca, testes position relative to both ventral sucker and ovary, cirrus-sac shape, pars prostatica shape and its extension inside

cirrus, genital pore positions, vitelline follicles distribution and its posterior extension, seminal receptacle shape, ovary shape and posterior extension of the uterus, were caused by differential treatment of the specimens. Regarding the specimens' age, we think it has another small effect on the observed variations in *A. callyodontis* particularly the size body, uterus extension, and seminal receptacle, vitelline follicle, and the growing degree of embryonated eggs, oesophageal glands, and pars prostatica cells.

Species of *Apharyngogyliauchen* parasitize the intestine of herbivorous marine teleosts within the families Scaridae and Labridae distributed in the Indo-West Pacific region (Hall and Cribb, 2005). Previously *A. callyodontis* described forms found parasitizing the intestine of 3 Scarid fish; an unidentified parrotfish, "*Callyodon* sp." (Yamaguti, 1942), *Hipposcarus harid* (Nagaty, 1956; Ramadan, 1986; Rabie and Ahmed, 2000) and *Scarus ghobban* (Rabie and Ahmed, 2000). In addition, 2 labrid fish harbored *A. callyodontis*; *Anampses caeruleopunctatus* (Ramadan, 1986) and *Cheilinus abudjubbe* (Rabie and Ahmed, 2000). The present study reports *A. callyodontis* from another a scarid fish, *Scarus psittacus* from the same geographic locality (Northern Red Sea off Egypt) [See table.1]. To our knowledge, only two digenean parasites are known to infect *Scarus psittacus*; both *Plesioschistorchis callyodontis* (Yamaguti, 1942) and *Plesioschistorchis haridis* (Nagaty, 1957) were reported by Blend et al (2017) from off Northern Red Sea, off Sharm El-Naga, Makadi Bay and El-Halaka Fish Market, southern Hurghada, Egypt (respectively).

#### Acknowledgments

We are grateful to the Zoology Department, Faculty of Science, South Valley University, Qena, Egypt, for the cooperation and help given to Y.F.M.K. We

thank Dr. Chuck Blend, Corpus Christi Museum of Science & History, 1900 N. Chaparral St., Corpus Christi, Texas 78401, USA and Dr. Norman Dronen Laboratory of Parasitology, Department of Wildlife and Fisheries Sciences, Texas A&M University, 2258 TAMU, College Station, Texas 77843-2258, USA, who provided Y.F.M.K. needed literature and kindly help.
